

# SYSTEM AND METHOD FOR JOINT RESURFACE REPAIR

2 This application is a continuation-in-part application under 37 C.F.R. § 1.53(b) of  
3 application Serial No. 09/846,657, filed May 1, 2001, which claims priority from U.S.  
4 provisional application Serial No. 60/201,049, filed May 1, 2000.

## FIELD OF THE INVENTION

6 This invention relates to devices and methods for the repair of defects that occur  
7 in articular cartilage on the surface of bones, particularly the knee.

## BACKGROUND OF THE INVENTION

9 Articular cartilage, found at the ends of articulating bone in the body, is typically  
10 composed of hyaline cartilage, which has many unique properties that allow it to function  
11 effectively as a smooth and lubricious load-bearing surface. However, when injured,  
12 hyaline cartilage cells are not typically replaced by new hyaline cartilage cells. Healing  
13 is dependent upon the occurrence of bleeding from the underlying bone and formation of  
14 scar or reparative cartilage called fibrocartilage. While similar, fibrocartilage does not  
15 possess the same unique aspects of native hyaline cartilage and tends to be far less  
16 durable.

17 Hyaline cartilage problems, particularly in knee and hip joints, are generally  
18 caused by disease such as occurs with rheumatoid arthritis or wear and tear  
19 (osteoarthritis), or secondary to an injury, either acute (sudden), or recurrent and chronic  
20 (ongoing). Such cartilage disease or deterioration can compromise the articular surface  
21 causing pain and further deterioration of joint function. As a result, various methods  
22 have been developed to treat and repair damaged or destroyed articular cartilage.

1 For smaller defects, traditional options for this type of problem include non-  
2 operative therapies (e.g., oral medication or medication by injection into the joint), or  
3 performing a surgical procedure called abrasion arthroplasty or abrasion chondralplasty.  
4 The principle behind this procedure is to attempt to stimulate natural healing. At the  
5 defect site, the bone surface is abraded, removing approximately 1 mm. or less using a  
6 high-speed rotary burr or shaving device. This creates an exposed subchondral bone bed  
7 that will bleed and will initiate a fibrocartilage healing response. Although this  
8 procedure has been widely used over the past two decades and can provide good short  
9 term results, (1-3 years), the resulting fibrocartilage surface is seldom able to support  
10 long-term weight bearing, particularly in high-activity patients, and is prone to wear.

11 Another procedure, referred to as the “microfracture” technique, incorporates  
12 similar concepts of creating exposed subchondral bone. During the procedure, the  
13 cartilage layer of the chondral defect is removed. Several pathways or “microfractures”  
14 are created to the subchondral bleeding bone bed by impacting a metal pick or surgical  
15 awl at a minimum number of locations within the lesion. By establishing bleeding in the  
16 lesion and by creating a pathway to the subchondral bone, a fibrocartilage healing  
17 response is initiated, forming a replacement surface. Results for this technique are  
18 generally similar to abrasion chondralplasty.

19 Another known option to treat damaged articular cartilage is a cartilage transplant,  
20 referred to as a Mosaicplasty or osteoarticular transfer system (OATS) technique. This  
21 involves using a series of dowel cutting instruments to harvest a plug of articular cartilage  
22 and subchondral bone from a donor site, which can then be implanted into a core made  
23 into the defect site. By repeating this process, transferring a series of plugs, and by

1 placing them in close proximity to one another, in mosaic-like fashion, a new grafted  
2 hyaline cartilage surface can be established. The result is a hyaline-like surface  
3 interposed with a fibrocartilage healing response between each graft.

4 This procedure is technically difficult, as all grafts must be taken with the axis of  
5 the harvesting coring drill being kept perpendicular to the articular surface at the point of  
6 harvest. Also, all graft placement sites must be drilled with the axis of a similar coring  
7 tool being kept perpendicular to the articular surface at the point of implantation. Further,  
8 all grafts must be placed so that the articular surface portion of these cartilage and bone  
9 plugs is delivered to the implantation site and seated at the same level as the surrounding  
10 articular surface. If these plugs are not properly placed in relation to the surrounding  
11 articular surface, the procedure can have a very detrimental effect on the mating articular  
12 surface. If the plugs are placed too far below the level of the surrounding articular  
13 surface, no benefit from the procedure will be gained. Further, based on the requirement  
14 of perpendicularity on all harvesting and placement sites, the procedure requires many  
15 access and approach angles that typically require an open field surgical procedure.  
16 Finally, this procedure requires a lengthy post-operative non-weight bearing course.

17 Transplantation of previously harvested hyaline cartilage cells from the same  
18 patient has been utilized in recent years. After the cartilage is removed or harvested, it is  
19 cultured in the lab to obtain an increase in the number of cells. These cells are later  
20 injected back into the focal defect site and retained by sewing a patch of periosteal tissue  
21 over the top of the defect to contain the cells while they heal and mature. The  
22 disadvantages of this procedure are its enormous expense, technical complexity, and the  
23 need for an open knee surgery. Further, this technique is still considered somewhat

1 experimental and long-term results are unknown. Some early studies have concluded that  
2 this approach offers no significant improvement in outcomes over traditional abrasion  
3 and microfracture techniques.

4 U.S. Patent No. 5,782,835 to Hart et al. discloses an apparatus and method for  
5 repair of articular cartilage including a bone plug removal tool, and a bone plug  
6 emplacement tool. The method of repairing defective articular cartilage includes the  
7 steps of removing the defective cartilage and forming a hole of sufficient depth at the site.  
8 A bone plug comprising intact bone and cartilage adhering thereto is removed from a  
9 bone lacking defective cartilage is placed in the hole at the site of the damage.

10 U.S. Patent No. 5,413,608 to Keller discloses a knee joint endoprosthesis for  
11 replacing the articular surfaces of the tibia comprising a bearing part which is anchored  
12 on the bone having an upper bearing surface and a rotatable plateau secured on the  
13 bearing surface and forming a part of the articular surface to be replaced. A journal rises  
14 from the bearing surface and cooperates with a bore in the plateau to provide lateral  
15 support.

16 U.S. Patent No. 5,632,745 to Schwartz describes a method of surgically  
17 implanting into a site a bio-absorbable cartilage repair assembly. The assembly includes  
18 a bio-absorbable polygonal T-shaped delivery unit having radial ribs to be mounted in the  
19 removed area and a porous bio-absorbable insert supported by and in the delivery unit.  
20 The method comprises the steps of preparing the site to receive the assembly by  
21 removing a portion of the damaged cartilage and preparing the site to receive the  
22 assembly by drilling and countersinking the bone. The assembly is inserted and seated

1 using an impactor in the drilled and countersunk hole in the bone until the assembly is  
2 flush with the surrounding articular surface.

3 U.S. Patent No. 5,683,466 to Vitale illustrates an articular joint surface  
4 replacement system having two opposing components. Each component has a tapered  
5 head piece for covering the end of a bone and for acting as an articular surface, an  
6 integrally formed screw stem of sufficient length to extend into the bone and inwardly  
7 angled bone grips on the underside of the head piece to allow fixation to the bone by  
8 compression fit. The partially spherical convex shaped exterior of the first component  
9 complements the partially spherical concave shaped exterior of the second component.

10 U.S. Patent No. 5,702,401 to Shaffer discloses an intra-articular measuring device  
11 including a hollow handle defining a first passageway and a hollow tube having a second  
12 passageway extending from the handle, the hollow tube carrying a projection at its distal  
13 end for seating on a fixed site and a probe disposed at the distal end of the hollow tube  
14 which may be directed to a second site, to enable measurement of the distance between  
15 the first and second sites.

16 U.S. Patent No. 5,771,310 to Vannah describes a method of mapping the three-  
17 dimensional topography of the surface of an object by generating digital data points at a  
18 plurality of sample points on said surface, each digital data point including a property  
19 value and a position value corresponding to a particular point representing the properties  
20 of the surface of the object. A 3-D transducer probe (e.g., a digitizer) is moved on or  
21 over the surface along a random path, and the sample points are digitized to generate a  
22 real-time topography or map on a computer screen of selected properties of the object,

1 including without limitation, surface elevation, indentation stiffness, elevation of sub-  
2 surface layers and temperature.

3 Prosthetics for total knee replacement (TKR), whereby the entire knee joint or a  
4 single compartment of the knee joint is replaced can be a common eventuality for the  
5 patient with a large focal defect. Although these patients are also managed with anti-  
6 inflammatory medications, eventual erosion of the remaining articular cartilage results in  
7 effusion, pain, and loss of mobility and/or activity for the patient. Problems encountered  
8 after implanting such prostheses are usually caused by the eventual loosening of the  
9 prosthetic due to osteolysis, wear, or deterioration of the cements used to attach the  
10 device to the host bones. Further, some prostheses used are actually much larger than the  
11 degenerated tissue that needs to be replaced, so that extensive portions of healthy bone  
12 are typically removed to accommodate the prostheses. Patients who undergo TKR often  
13 face a long and difficult rehabilitation period, and the life span of the TKR is accepted to  
14 be approximately 20 years. Accordingly, efforts are made to forgo the TKR procedure  
15 for as long as possible.

16 Accordingly, there is a need for an improved joint surface replacement system  
17 that would be effective in restoring a smooth and continuous articular surface and that  
18 would also be as durable as the former hyaline cartilage surface, within the context of a  
19 minimally invasive procedure that allows for a nearly immediate return to activity,  
20 restoration of lifestyle, and pain relief.

## **SUMMARY OF THE INVENTION**

2 The present invention provides tools and methods for mapping and measuring the  
3 articular surface of a joint (or of any bony surface) and for fabricating a prosthetic device  
4 based on this recorded data.

5 In one method consistent with the invention, once the defect of the chondral  
6 surface has been identified, a guide pin is inserted arthroscopically. A fixation screw  
7 having a tapered distal tip and an aggressive distal end thread form is then driven into the  
8 subchondral bone in relation to a reference axis that is approximately central to the  
9 defect. The fixation device also serves to define a tangent point to the surrounding  
10 articular surface. The screw is driven by a socket type driver that engages a hex-shaped  
11 proximal extension. A further cylindrical proximal extension of the screw (or other  
12 mating feature, e.g., a recess in the screw) that eventually serves as a fixation element for  
13 the surface prosthetic is at this time concealed with a cover (or other mating feature  
14 corresponding to the mating feature of the screw, e.g., a plug for mating with a screw  
15 having a recess as its mating feature) having a radius proximal end. One or more  
16 milled slots run the length of the uniform diameter portion of the screw.

17 Under arthroscopic view, the screw depth is adjusted so that the radiused cover  
18 surface is positioned tangent to the radius that defines the existing articular surface. At  
19 this time, the guide pin is removed and the knee is articulated. The depth positioning of  
20 the radiused cover establishes an origin or reference point for all future measuring,  
21 cutting, and prosthetic machining operations. Arthroscopic examination is carried out to  
22 confirm positioning.

1       A measuring tool is inserted on the reference axis. A central element of the  
2   measuring tool is a static post that establishes the axial location of origin. By rotating  
3   the outer arm or outrigger of the measuring tool relative to the static post while also  
4   maintaining contact with the articular surface, an axial displacement or Z dimension can  
5   be established relative to the origin for any point along the known radial sweep of the  
6   outrigger to determine the final geometry of the prosthetic surface which fits within the  
7   defect. These Z dimensions can be recorded in real time with conventional dial gauge  
8   indicators, or with digital recording devices, or by using marking techniques. Although  
9   numerous points may be taken, ideally a minimum number of points are taken to  
10   accurately define the target articular surface.

11       Locating surfaces or features created on the screw, (or alternatively, on the radius  
12   cover, as described in alternative embodiments herein), correlate to some surface or  
13   feature on the measuring tool and allow the measurement of the rotational position of the  
14   points about the axis with respect to the locating surfaces. Data recorded during the  
15   mapping procedure can then be entered into parametric engineering design software or  
16   similar algorithm to define a three dimensional surface matched to the bearing surface  
17   geometry to be implanted and reproduce the anatomic contours mapped.

18       An alternative measuring device for obtaining the articular surface dimension  
19   includes an outer marking element and an inner recording element. The marking element  
20   includes a sharp indenting mechanism which when pressed by the surgeon creates a  
21   depression or mark in the relatively soft surface of the recording element, which deforms  
22   at these marked points so that they can be utilized as patient data. The recording  
23   element also includes a surface that corresponds to the surface of the proximal extension

1 of the fixation screw. During the mapping procedure, data points are established of the  
2 rotational position of the mapped articular surface relative to the screw. These data  
3 points are translated to the implant geometry so that the accurate rotational location of the  
4 implant relative to the screw is maintained.

5 In order to secure the implant to the fixation screw, a precision taper (or other  
6 component of a mating feature) is machined into a protrusion (or other component of a  
7 mating feature) on the back of the device. The implant may be constructed of cobalt  
8 chromium, or other materials. The implant may also include a slight outward taper or  
9 protrusion along the diametrical surface to enhance load bearing or load transfer  
10 properties of the implant to surrounding bone. Additionally, a series of radial cuts may  
11 create surfaces that increase resistance of the implant to rotational forces. These features  
12 may be located around the outer diameter of the implant.

13 In another aspect, the invention includes a compass instrument for measurement  
14 and surface preparation of the implant target site subsequent sizing of the implant. This  
15 compass instrument is configured so that it can be delivered to the site arthroscopically,  
16 and when coupled to the axis defined by the guide pin it can be used for measuring and  
17 cutting operations.

18 In another embodiment, the compass instrument consists of a handle, a cannulated  
19 shaft that extends through the handle, and a cannulated distal offset arm configured to  
20 serve as a linearly adjustable mounting tool for a series of cutting blades, boring blades,  
21 or measuring probes.

22 With the guide pin advanced through the instrument shaft, when fitted with a  
23 blade, a fixed length from the rotational or reference axis to the cutting blade's cutting

1 surface is established. This defines the radius that is effected as the instrument is rotated  
2 around the guide pin, and corresponds to the overall diameter of the implant. This sharp  
3 cutting blade is used to circumscribe and cleanly cut the surrounding articular cartilage.

4 In another aspect, the invention features a bone cutting or scoring instrument  
5 whereby the bone-cutting instrument is positioned on the guide pin reference axis and is  
6 used to prepare the target site to match in configuration and dimension the contacting  
7 surface of the implant. The matching fit between the bone surfaces of the prepared  
8 target site and the bone contacting surfaces of the implant can advantageously ensure  
9 long term clinical results with the implant, as poor quality of fit between bone surfaces  
10 and bone contacting surfaces of traditional orthopedic prosthetic devices has been noted  
11 to contribute to early clinical failures.

12 Following fabrication of the implant, a second surgical procedure is performed.  
13 The radiused cover is removed exposing a precision taper (or, alternatively, the cover  
14 may be removed during the first procedure). A pin with a distally mounted element is  
15 placed through the central lumen of the fixation screw so that the distally mounted  
16 element is secured into the screw. This element carries one or more suture strands that  
17 now trail from the fixation screw. The sutures are then threaded through the implant and  
18 a knot or bead may be created proximal to the implant. By continuing to manipulate and  
19 tension the suture strands, the implant can be brought coaxial to the fixation screw. Once  
20 coaxial, the implant is aligned via engagement of the keyed elements and driven into  
21 place with a plastic driving rod and mallet. Finally, through the guide aperture on the  
22 surface of the implant, bone cement may be injected to enhance the contact surface  
23 between the implant and the subchondral bone.

1        In another aspect, the invention further features a driver whereby the implant is  
2        connected to the driver via a holder and a tether element, such as a suture or wire. The  
3        implant and the driver are then inserted arthroscopically. Tension is then applied to the  
4        tether element so that the implant is drawn back and seated on the driver. The implant  
5        can then be controllably delivered to the prepared target site. The seat portion of the  
6        driver may comprise a material that may be impacted to seat the implant without  
7        damaging the implant surface.

8        In one aspect, a guide device for locating a guide pin or wire substantially normal  
9        with respect to an articular surface of bone comprises a cannulated shaft having a distal  
10       end and a central longitudinal axis; and a ring portion coupled to the distal end of the  
11       shaft, the ring portion comprising a planar distal contact surface comprising a plurality of  
12       points radially extending from any given point along the central longitudinal axis of the  
13       shaft.

14       In another aspect, a guide device for locating a guide pin or wire substantially  
15       normal with respect to an articular surface of bone having an anterior-posterior (AP)  
16       curve and a medial-lateral (ML) curve comprises a cannulated outer shaft and a  
17       cannulated inner shaft. The outer shaft has a central longitudinal axis and an outer  
18       component at its distal end, the outer component comprising a set of arms, and the  
19       cannulated inner shaft is slidably disposed within the cannula of the outer shaft, the inner  
20       shaft having an inner component at its distal end and sharing the central longitudinal axis  
21       of the outer shaft, the inner component comprising a set of arms.

22       In method form, a method for replacing a portion of an articular surface of bone  
23       comprises defining an axis generally normal to the portion of an articular surface of bone

1 to be replaced; excising at least the portion to be replaced by cutting the articular surface  
2 radially symmetrically about the axis, thereby creating an excised portion of the articular  
3 surface; selecting an implant corresponding to the dimensions of the excised portion from  
4 a set of variously-sized implants; and installing the selected implant into the excised  
5 portion.

6 In method form, a method for replacing a portion of an articular surface of bone  
7 having an anterior-posterior (AP) curve and a medial-lateral (ML) curve comprises  
8 defining an axis generally normal to the portion of an articular surface of bone to be  
9 replaced using an anterior-posterior (AP) curve and a medial-lateral (ML) curve of the  
10 articular surface; excising at least the portion to be replaced by cutting the articular  
11 surface radially symmetrically about the axis, thereby creating an excised portion of the  
12 articular surface; selecting an implant corresponding to the dimensions of the excised  
13 portion from a set of variously-sized implants; and installing the selected implant into the  
14 excised portion.

15 In a further aspect, a tool for holding an implant comprises an activatable suction  
16 source; and an elastomeric suction tip adapted to receive an implant, the tip being  
17 coupled to the suction source.

18 In method form, a method for holding an implant comprises coupling a suction  
19 source to an implant; and activating the suction source.

20 In method form, a method for delivering an implant comprises coupling a suction  
21 source to an implant; activating the suction source; approximating the implant to its  
22 delivery site; and applying a force to the implant in the direction of the delivery site.

1           In yet another aspect, a tool for removing an implant from its delivery site  
2   comprises a cylindrical structure having a distal end; the distal end comprising a  
3   longitudinal central axis, a circular blade portion having a leading edge comprising a  
4   blade surface turned on the distal-most portion, and a lip portion disposed proximally  
5   with respect to the leading edge; and a plurality of slits parallel to the longitudinal central  
6   axis of the distal end formed along the length of the cylindrical structure, so as to permit  
7   sufficient outward expansion of the distal end to accommodate the top edge of an implant  
8   therein.

9           In method form, a method for removing an implant from its delivery site  
10   comprises disposing the lip portion of the leading edge of the distal end of a removal tool  
11   over the upper edge of an implant seated in its delivery site; and applying a pulling force  
12   to the removal tool.

13           In still another aspect, a device for mapping a portion of an articular surface of  
14   bone comprises a handpiece, an inner shaft, a contact tip, a rotary measuring element, and  
15   a linear measuring element. The inner shaft runs along the length of and is disposed  
16   within the handpiece and comprises a mating feature for mating with a fixed element  
17   located substantially normal with respect to an articular surface. The contact tip is  
18   slidably and rotatably disposed about the inner shaft. The rotary measuring element is  
19   coupled to and rotating with the contact tip. The linear measuring element is nested  
20   concentrically and coaxially to the rotary measuring element, and coupled to and moving  
21   linearly with the contact tip.

22           A generic bone implant, or set of standardized implants, may further be created  
23   based on using a guide device to develop an axis normal to an articular surface of bone

1 and collecting only one or two data points. A generic cutting tool may be used to cut the  
2 bone to a point where a generic implant can be used. Several improved tools relating to  
3 the procedure for using such an implant, as well as methods for using implants consistent  
4 with the invention are further described hereinbelow, including: single-axis and biaxial  
5 drill guide tools and methods, generic single-axis implant methods and devices, generic  
6 biaxial implant methods and devices, tools and methods for holding or delivering an  
7 implant, removal or revision tools and methods, digital measuring systems and methods,  
8 and set of measuring gauges for determining the appropriate implant dimensions.

9

10 **DESCRIPTION OF THE DRAWINGS**

11 Figure 1 is a fragmentary side view of a knee having therein an exemplary  
12 assembled fixation device and implant of the joint surface repair system surgically  
13 implanted by the method in one embodiment of the present invention;

14 Figure 2a is an exploded side view of an exemplary fixation screw and hex-  
15 shaped proximal extension in one embodiment of the present invention;

16 Figure 2b is an exploded perspective view of an exemplary fixation screw and  
17 hex-shaped proximal extension in one embodiment of the present invention;

18 Figure 3a is a side view of an exemplary assembled fixation screw and hex shaped  
19 extension in one embodiment of the present invention;

20 Figure 3b is an exploded perspective view of another exemplary fixation screw  
21 and implant in one embodiment of the present invention;

1       Figure 4a is a perspective view of the upper surface of an exemplary implant in  
2       one embodiment of the present invention;

3       Figure 4b is a side view of an exemplary implant in one embodiment of the  
4       present invention;

5       Figure 4c is a perspective view of the lower surface of an exemplary implant in  
6       one embodiment of the present invention;

7       Figure 5a is a side view of an exemplary assembled fixation device and implant in  
8       one embodiment of the present invention;

9       Figure 5b is a perspective view of an assembled fixation device and implant in  
10      one embodiment of the present invention;

11      Figure 5c is a perspective view of the upper surface of an exemplary implant, in  
12      one embodiment of the present invention;

13      Figure 5d is a perspective view of the lower surface of an exemplary implant, in  
14      one embodiment of the present invention;

15      Figure 6a is a sectional view of a knee having damaged articular cartilage,  
16      showing an exemplary guide pin drilled into the central portion of the defect and an  
17      arthroscope being disposed adjacent thereto, in a surgical procedure consistent with one  
18      embodiment of the present invention;

19      Figure 6b is a side view of the distal tip of an exemplary drill device for boring a  
20      pilot hole to receive an exemplary fixation screw, in one embodiment of the present  
21      invention;

1                   Figure 7a is a sectional view of a knee having damaged articular cartilage,  
2                   showing an exemplary fixation screw being driven into the defect by an exemplary socket  
3                   type driver arranged on the guide pin, in a surgical procedure consistent with one  
4                   embodiment of the present invention;

5                   Figure 7b is a side view of the exemplary fixation screw, socket type driver and  
6                   guide pin of Figure 7a, illustrating the hex shaped proximal extension in a cross-sectional  
7                   view, in a surgical procedure consistent with one embodiment of the present invention;

8                   Figure 8a is a perspective view of a knee having damaged articular cartilage,  
9                   showing an exemplary fixation screw and hex-shaped proximal extension implanted in  
10                  the defect after removal of an exemplary socket type driver and guide pin, in a surgical  
11                  procedure consistent with one embodiment of the present invention;

12                  Figure 8b is a sagital view of the exemplary fixation screw and hex-shaped  
13                  proximal extension of Figure 8a implanted in the defect after removal of an exemplary  
14                  socket type driver and guide pin, in a surgical procedure consistent with one embodiment  
15                  of the present invention;

16                  Figure 8c is a perspective view of an exemplary fixation screw, proximal  
17                  extension and cover, in one embodiment of the present invention;

18                  Figure 9a is a sectional view of an exemplary fixation screw and hex-shaped  
19                  proximal extension implanted in the defect with the exemplary guide pin replaced and an  
20                  exemplary measuring tool arranged thereon, in a surgical procedure consistent with one  
21                  embodiment of the present invention;

1           Figure 9b is a side partial cross-sectional view of the exemplary fixation screw  
2    and hex-shaped proximal extension of Figure 9a implanted in the defect with the  
3    exemplary guide pin replaced and an exemplary measuring tool arranged thereon, in a  
4    surgical procedure consistent with one embodiment of the present invention;

5           Figure 9c is a perspective view of an exemplary fixation screw and proximal  
6    extension, with the cover removed, in one embodiment of the present invention;

7           Figure 10a is a sectional view of an exemplary fixation screw and hex-shaped  
8    proximal extension implanted in the defect, after removal of the hex-shaped proximal  
9    extension, with an exemplary pin and suture strands placed therethrough, in a surgical  
10   procedure consistent with one embodiment of the present invention;

11          Figure 10b is a side partial cross-sectional view of the exemplary fixation screw  
12    and hex-shaped proximal extension of Figure 10a, implanted in the defect, with an  
13    exemplary pin and suture strands placed therethrough, in a surgical procedure consistent  
14    with one embodiment of the present invention;

15          Figure 11a is a sectional view of an exemplary fixation screw implanted in the  
16    defect, with an exemplary pin and suture strands placed therethrough, showing the  
17    implanted fixation screw with the implant being tensioned on the suture strands, in a  
18    surgical procedure consistent with one embodiment of the present invention;

16 an exemplary digital measuring system in one embodiment of the present invention.

17            **DETAILED DESCRIPTION OF THE EMBODIMENTS**

18          As an overview, Figure 1 shows a surgically implanted articular joint surface  
19 repair system consistent with the present invention. As shown, the assembled fixation  
20 device includes fixation screw 10, implant 40, and anchoring pin 5, implanted in the  
21 defect in the medial femoral chondral surface 55 of knee 50. Implant 40 is configured so  
22 that bearing or bottom surface 41 of the implant reproduces the anatomic contours of the  
23 surrounding articular surface of the knee 50.

1 As illustrated in Figures 2a, 2b and 3a, fixation screw 10 comprises threads 12  
2 running the length of the screw from tapered distal tip 11 to hex-shaped drive 15. In the  
3 embodiment shown, the screw includes a tapered distal end 11, and aggressive distal  
4 threads 12, so that, as screw 10 is driven into the subchondral bone 100 (as shown in  
5 Figure 7a) the screw dilates open and radially compress the subchondral bone, increasing  
6 its local density and thereby increasing the fixation strength of the screw. The screw 10  
7 may taper down to the distal end 11, and the diameter of the screw may become greater  
8 and more uniform at the center thereof, so that adjustment of the depth of the screw 10  
9 with respect to the subchondral bone 100 does not significantly further increase or  
10 decrease the compression of the subchondral bone.

11 One or more milled slots 13 run the length of the uniform diameter portion of the  
12 screw 10. Slots 13 ensure that as healing or tissue in-growth begins, migrational or  
13 rotational movement of the screw is inhibited. The screw 10 is configured to be driven  
14 by a female or socket type driver 2 as shown in Fig. 7b, which engages a hex-shaped  
15 drive 15 located toward the proximal end 17 of the screw. A cylindrical proximal  
16 extension 14 (which may, alternatively, be a recess 303 which mates with a plug or other  
17 protrusion on the implant surface, as shown in Figure 8c) extends from hex-shaped drive  
18 15, which eventually serves as a fixation element for surface prosthetic implant 40.  
19 Through hole 16 runs through the central axis of the screw. Hex-shaped cover 30 (which  
20 may, alternatively, be a plug 301, for mating with a fixation element 302 having a recess,  
21 as shown, e.g., in Figures 3b, 8c, and 9c, and described in the following paragraph) is  
22 configured to engage the cylindrical proximal extension 14 of the screw 10 to prevent  
23 exposure of the cylindrical extension from inadvertent contact or damage. The hex-

1 shaped cover 30 is finished with a radiused proximal end 31 that assists in the visual  
2 determination of the correct depth setting of the screw. Through hole 32 in the hex-  
3 shaped cover 30 corresponds with through hole 16 in the fixation screw 10.

4 Alternatively, as shown in Figures 3b, 8c, and 9c, the female-shaped cover may  
5 instead be a plug 301 having a male-shaped mating component 305, for mating with a  
6 fixation element 302 of a screw 10' having a recess 303. Additionally, the shape of the  
7 cover and plug, or other recessed, protruding, or mating components may be other than  
8 hexagonal, and those in the art will recognize that one of any number of shapes or  
9 configurations for such components may be employed in a device or method consistent  
10 with the invention.

11 Also, while many of the components described herein are cannulated, having  
12 guide apertures, through holes, and/or central lumina along their length, for disposing  
13 such components about a guide rod for proper location of the components with respect to  
14 the articular surface, it should be recognized that a suture 313 or other flexible element,  
15 or other guide feature may be used in place of a guide rod, or a guide rod or wire may be  
16 eliminated altogether from one or more steps consistent with the invention described  
17 herein. As shown in Figure 8c, the suture 313 may be fixedly or removably attached to  
18 the plug 301.

19 As shown in Figures 4a, 4b and 4c, implant 40 comprises lower bearing surface  
20 41, top surface 42 and protrusion 45 located centrally on the bottom surface. As the top  
21 surface 42 of the implant 40 is not a bearing surface, and instead is fixed into subchondral  
22 bone 100, a series of stepped machine cuts 43 following the contours of the defect are  
23 created. By creating stepped machine cuts 43 a contoured contact surface matching the

1 defect in the subchondral bone 100 is created. This contact surface results in an increased  
2 surface area that should enhance resistance to loosening of the implant 40 via rotational  
3 or translational loading. In the illustrated embodiment, the stepped cuts are shown as  
4 square cross-section cuts, but the cuts may be circular, triangular, or another  
5 configuration.

6 In order to secure the implant 40 to the fixation screw 10, precision taper 44 is  
7 machined into or onto a protrusion 45 on the top surface 42 of the implant. The  
8 precision taper 44 is configured to engage the cylindrical proximal extension 14 of the  
9 screw 10, once the hex-shaped cover 30 has been removed therefrom. Taper 44 may be  
10 mated with extension 14 so that a friction fit is provided between these surfaces. The  
11 assembled fixation device is shown in Figures 5a and 5b. Alternatively, other  
12 engagement mechanisms such as snap-fits, press-fits, threads, or coupling elements, for  
13 example, may also be used. In one embodiment, leading pin 47 arranged on the  
14 protrusion 45 assists penetration into subchondral bone. Also, in one embodiment, guide  
15 aperture 46 passes through the top 42 and bottom 41 surfaces of the implant 40, just  
16 slightly off center of the reference axis 20A. Alternatively, guide aperture 46 may be  
17 located in the center of the implant 40 and corresponds to through hole 16 running  
18 through the central lumen in the fixation screw 10. Bone cement may be injected  
19 through guide aperture 46 on the surface of the implant 40 and through hole 16 in the  
20 fixation screw 10, to enhance the contact surface between the device and the subchondral  
21 bone. In one embodiment, the implant is constructed of cobalt chromium, although other  
22 materials may be used, including implantable plastics. Additionally, biologically active  
23 coatings or surface treatments (e.g., to enhance bone ingrowth or improve wear

1 properties) may be utilized or combined as laminates, particularly with respect to the  
2 bearing surfaces and bone contacting surfaces. Further exemplary materials that may be  
3 used in fabricating an implant consistent with the invention are described hereinbelow.

4 As shown in Figure 3b, it is noted that precision taper 44 may be a male-shaped  
5 component 304 instead of the above-described female component 44. In this  
6 configuration, the male-shaped component 304 of the implant 40' is configured for  
7 mating with a fixation element 302 of the screw 10' having a recess 303 adapted to  
8 receive the male-shaped component 304.

9 By way of example, Figures 6a-13 depict one exemplary joint surface  
10 methodology of the present invention. Figure 6a shows a focal defect 1 of the articular  
11 surface 55 of the femoral chondyle bone of the knee 50. This defect is identified by  
12 arthroscope 25 inserted in the area of the defect 1 during a diagnostic arthroscopy or  
13 surgical arthroscopy. The disclosed surgical intervention begins by drilling a guide pin  
14 20 defining reference axis 20A into the central portion of the defect 1 via an incision 200  
15 typical of arthroscopic procedures. Placement of this pin may be done using visual,  
16 freehand techniques, or may be located centrally by using outer element 71 of a  
17 measuring tool 70 (as shown in Figures 9a and 9b), or other aiming device or technique,  
18 to define a center. This reference axis 20A serves to establish a working axis located  
19 central to the defect 1 for the procedures that follow, and arthroscope 25 may be used to  
20 view the joint for purposes of establishing a reference axis 20A generally perpendicular  
21 to and bisecting the existing articular surface 55 defined by radii 60 and 61, as shown in  
22 Figure 8b. Referring to Figure 7a, 7b, 8a and 8b, fixation screw 10 and hex-shaped cover  
23 30 are driven into the defect 1 in the subchondral bone 100 by socket-type driver 2

1 mounted over (i.e., about) guide pin 20 located on reference axis 20A. Under  
2 arthroscopic view, the depth of fixation screw 10 may be adjusted by driver 2 so that the  
3 bottom of the radiused surface 31 of the hex-shaped cover 30 is positioned tangent to the  
4 radii 60 and 61 that define the existing articular surface 55. The guide pin 20 is removed  
5 and the knee 50 is articulated through its range of motion to ensure that the height of the  
6 radiused surface 31 of the hex-shaped cover 30 is proper, since the prosthetic surface 41  
7 of the implant 40 is created also to be tangent to this radiused surface 31. The depth  
8 positioning of the radiused surface 31 of the hex-shaped cover 30 establishes a point of  
9 origin or a reference point for all future measuring and machining operations.  
10 Arthroscopic examination may be carried out from multiple arthroscopic views to  
11 confirm positioning.

12 A drill mechanism 306, as illustrated in Figure 6b, may be used to bore a pilot  
13 hole for receiving a fixation screw 10 (as shown, e.g., in Figures 2a, 2b and 3a). As  
14 shown, the drill may have a shank portion 307 and a bit portion 308. The bit portion 308  
15 may include a spiral or parabolic fluted tip 309 having proximal 310, medial 311, and  
16 distal 312 portions. The root diameter at the medial portion 311 is substantially equal to  
17 the diameter of the fixation screw 10, and the diameter decreases as the distal portion 312  
18 tapers away from the shank 307. The proximal portion 310 of the bit 308 may be used as  
19 a visual indicator during drilling, to determine the point at which the proper bore depth  
20 has been attained. The drill mechanism may have a central lumen (not shown) having a  
21 diameter slightly greater than the diameter of the guide pin 20 (as illustrated in Figure 6a)  
22 running along its length, so that, with the guide pin 20 in place, the drill 306 may be  
23 disposed about the guide pin 20 during drilling to ensure proper location of the pilot hole

1 with respect to the articular surface 55. Alternatively, a self-drilling or self-tapping  
2 screw, may be used, as those skilled in the art will recognize.

3 For surface preparation and accurate measurement of the implant site and the  
4 subsequent sizing of the implant, instrument 120 is provided. The compass instrument  
5 120 may be configured to serve as a mounting tool for a number of functional blades or  
6 tips and when located about the axis 20A, via guide rod 20, may be used for measuring  
7 and cutting operations. In the embodiment shown in Figure 15a, compass instrument 120  
8 includes handle 110, a cannulated shaft 111 that extends through the handle, and a  
9 cannulated distal offset arm 112. The instrument may be rigid in construction and may  
10 be a durable reusable and resterilizable instrument. The distal offset arm 112 is  
11 configured so that it can be introduced into a site through an incision 200 typical of an  
12 arthroscopic procedure. Once the distal offset arm 112 has fully penetrated the incision  
13 and enters the site, shaft 111 can be angularly repositioned so that it becomes more  
14 coaxial to the reference axis 20A and advanced in-line with the reference axis 20A  
15 towards the implant target site. While performing this maneuver to position the  
16 compass instrument 120, the guide pin 20 should be removed from its position in the  
17 defect 1. When compass 120 is in its proper position at or near the implant target site, the  
18 guide pin 20 is delivered through the instrument cannulation 113, re-establishing the  
19 working (reference) axis 20A used to define the implant geometry.

20 Referring to Figure 15b, within offset arm 112 is a slotted surface 114 for  
21 engaging a series of cutting blades 121, boring blades 124, or measuring probes 122. The  
22 slots 115 are configured so that said series of cutting blades 121, boring blades 124  
23 (Figure 17c), measuring probes 122, 123 (Figures 17a, 17b), or like elements may be

1 partially constrained or fixed in position such that they may be adjusted linearly along the  
2 length of the slotted surface 114 over a defined distance of travel. Intersecting the plane  
3 of travel defined by slotted surface 114 and slots 115, is the cannulation 113.

4 As illustrated in Figure 16, when fitted with a cutting blade 121, and with the  
5 guide pin 20 advanced through the shaft 113 of instrument 120, so that the guide pin  
6 passes through a closely sized hole 116 in the cutting blade, the blade's position becomes  
7 fully constrained. When constrained in this fashion, a fixed length from the rotational or  
8 reference axis 20A to the cutting surface 117 of cutting blade 121 is established. This  
9 defines the radius that is effected as the instrument 120 is rotated around the guide pin 20,  
10 and corresponds to the overall diameter of the implant 40 that is delivered to the fully  
11 prepared site. The cutting blade 121 is used to circumscribe and cleanly cut the  
12 surrounding articular cartilage.

13 In an alternative embodiment, as shown in Figures, 17a and 17b, blade 123 and  
14 measuring probe 122, respectively, may have multiple holes 118 that defines that  
15 probe/blade's functional diameter. In addition, the blades may be specifically configured  
16 so that staged or sequential cuts of varying depths and diameters can be performed within  
17 the procedure. Also, such a blade can be configured by providing a readable scale 119  
18 corresponding to the hole 118 pattern, so that the surgeon may determine and set the  
19 appropriate diameter as needed by positioning the guide pin 20 in the corresponding hole.  
20 As the readable scale 119 may be located on the blade 123 with respect to the blade's  
21 cutting surface 117, a high degree of positional accuracy may be achieved as the scale  
22 may be defined specifically for each type of blade. This approach creates an inexpensive  
23 means of providing sharp blades of varying diameters and varying blade types without a

1 large inventory of size- and type-specific blades. Referring to Figure 17b, rounded tip  
2 109 of measuring probe 122 can be used to determine the appropriate diameter and can  
3 be similarly sized and secured in the compass instrument 120. The tip 109 may be  
4 rounded to prevent marring of the articular surface. Figure 17c shows a boring bit or  
5 bone cutting blade 124 with multiple cutting surfaces 107 and 108 configured in this  
6 fashion.

7       Turning now to Figures 9a and 9b, with the guide pin 20 replaced, a measuring  
8 tool 70 is inserted so that the reference axis 20A is utilized. A central element of the  
9 measuring tool 70 is a post 75 that is static, establishes the axial location of the point of  
10 origin 80, and mates with a rotational location feature within the screw 14. By rotating  
11 the outer arm or outrigger 71 of the measuring tool 70 relative to the static post 75 while  
12 also maintaining contact with the articular surface 55, an axial displacement or Z  
13 dimension can be established relative to the point of origin 80 for any point along the  
14 sweep of the outrigger. Each such Z dimension may be recorded in real time with  
15 conventional dial gauge indicators 72 or with a digital recording device, such as disclosed  
16 in U.S. Patent No. 5,771,310 to Vannah, or by using other known marking techniques.  
17       Although numerous points may be taken, ideally a minimum number of points are taken  
18 to define accurately the target articular surface. In other embodiments, multiple  
19 outriggers that embody different diameters or an adjustable outrigger may be used to map  
20 larger defects, and also to determine the final diameter of the prosthetic surface that fits  
21 within the defect. It is noted that the measuring tool may comprise a spring or other  
22 tensioning device (not shown), for urging the outrigger distally with respect to the handle  
23 of the tool. In this aspect, the outrigger is manually pressed against the articular cartilage,

1 so as to maximally compress the articular cartilage upon recording data points, so that the  
2 data points taken are of a maximally “loaded” or “compressed” dimension.

3 Figures 20a, 20b and 20c show an alternative measuring and mapping device 210  
4 for obtaining the articular surface dimension, comprising housing 217 and a recording  
5 element 218. As shown in Figure 20a, recording element 218 includes upper portion 219,  
6 flange 222 and calibrated lower portion 220. Key-shaped surface 221 located at distal  
7 end 225 of recording element 218 is configured to engage a reciprocal key-shaped  
8 surface in the proximal extension 14 of fixation screw 10, or, for example, a key shaped  
9 cover arranged on the proximal end of the screw (not shown). The upper portion 219 of  
10 recording element 218 may be constructed of a relatively soft or other deformable  
11 material that can be marked with patient data. Cannulated shaft 223 runs through the  
12 central lumen of the recording element 218. As shown in Figure 20b, housing 217  
13 includes a marking mechanism 224 located on the upper portion 226 of the housing, at or  
14 within window or aperture 230. An indexing indicator 228 is located on the lower  
15 portion 227 of the housing 217, at window or opening 229.

16 Turning to Figure 20c, recording element 218 is inserted in housing 217 of  
17 measuring and mapping device 210, so that the distal end 225 of recording element 218  
18 appears through opening 232. Tensioning means (not shown) in the device 210, enables  
19 recording element 218 to move longitudinally within housing 218. With the guide pin 20  
20 replaced, the measuring device 210 is inserted on the guide pin on reference axis 20A so  
21 that key-shaped surface 221 engages the corresponding keyed surface of the screw and is  
22 maintained in static position thereby. These key-shaped surfaces establish the rotational  
23 position of the articular surface points to be mapped relative to the screw. During the

1 measuring and mapping procedure, the surgeon rotates housing 217 and outer arm or  
2 outrigger 231 located at the distal end 235 of housing. By depressing marking  
3 mechanism 224, a series of depressions or marked points 240 is established in the  
4 relatively soft surface of the upper portion 219 of the recording element 218, which  
5 deforms at these marked points so that they can be utilized as patient data. Indexing  
6 indicator 228 and calibrated lower portion 220 of recording element 217 allow for  
7 controlled rotational movement between housing 217 and recording element 218. In  
8 this way, the rotational position of the mapped articular surface points 235 relative to the  
9 screw 10 as appreciated by outer arm of outrigger 231, is translated to the implant  
10 geometry as a feature so that the accurate rotational location of the implant 40 relative to  
11 the screw 10 is maintained.

12 For example, as shown in Figures 8b and 9b, to accurately reproduce the two radii  
13 60 and 61 that locally define the articular surface 55, four points, 81a and 81b, and 82a  
14 and 82b, and the point of origin 80 are recorded. As any three points in a single plane  
15 define a curve, by recording points 81a and 81b and the point of origin 80, radius 60  
16 defining the medial-lateral aspect 68 of the chondyle can be determined. By recording  
17 points 82a and 82b and the point of origin 80, the radius 61 defining the anterior-posterior  
18 aspect 69 of the chondyle can be determined. In the example provided, in order to  
19 maintain the relationship between these two defined radii, 60 and 61, the measuring tool  
20 70 is constructed so that it can be accurately indexed from a fixed starting point along 90  
21 degree intervals to capture or map said four points 81a, 81b, 82a and 82b, over the course  
22 of its revolution.

1 Locating surfaces or features created on the radius cover 30, or along some length  
2 of the fixation screw 10, hex-shaped drive surface of the screw 14 or on the cylindrical  
3 proximal extension (or recess) of the screw 14, correlate to some surface or feature on the  
4 measuring tool 70 and allow the measurement of the rotational position of the four  
5 measured points 81a, 81b, 82 and 82b, about the reference axis 20A with respect to said  
6 locating surfaces. This data becomes important in configuring the implant 40 with respect  
7 to the fixation screw 10 so that the proper orientation of said measured points to  
8 fabricated geometry is maintained. Of course, such measuring tool can be configured to  
9 measure any number of points at any interval desired.

10 While the measurements are illustrated in Figures 9a and 9b as being taken from  
11 the bottom of the radiused surface 31 of the hex-shaped cover 30 of the screw, the  
12 measurements may alternatively be taken from the top of the screw 10' itself, as shown in  
13 Figure 9c. As shown, in this embodiment, a key 315 or other alignment feature may be  
14 provided, to indicate the starting point for taking measurements. In this configuration,  
15 the measuring tool used, as well as the implant manufactured, both have a mating feature  
16 matching the key 315, for properly locating the starting point of the measurements taken  
17 and thereby subsequently properly aligning the implant with respect to the defect.

18 Other embodiments of measuring and recording tools are possible. One such  
19 embodiment of a measuring and recording tool 210' is shown in Figures 20d – 20i. As  
20 shown, measuring tool 210' comprises a handle 316, outer shaft 333, inner shaft 330,  
21 scroll 317, a tactile feedback portion 318, ring 320 having a button 321 in communication  
22 with a sharp marking point 326 thereunder, a rotating portion 322 having a rotational lock  
23 323 which prevents rotation of the rotating portion 322 when engaged, and an outrigger

1 portion 324. The handle 316 remains fixed during rotation and does not move while the  
2 tool 210' is used for measuring. Instead, the rotating portion 322 is rotated to a start  
3 position and the rotational lock is engaged, securing the rotating portion 322 to the tactile  
4 feedback portion 318 and thereby preventing its rotation. The scroll 317 is configured  
5 with a notch 325 or similar mating feature to align with a corresponding mating feature  
6 (not shown) of the handle 316, such that the scroll can only align at one rotational point,  
7 at 0 degrees, with respect to the handle 316 upon loading into the tool 210', e.g., by  
8 "snapping" into place. The sharp marking point 326 located inside the ring 320 under the  
9 sharp marking point 326, marks a point of depression into the scroll 317 while first button  
10 321 is being depressed. Instead of marking by making depressions on a scroll or spool,  
11 marking could alternatively be made upon nearly any surface, e.g., using ink to record on  
12 a paper spool, or by digital means.

13 As shown in Figures 20f and 20g, outer shaft 333, which is fixedly coupled to  
14 rotating portion 322, outrigger 324 and ring 320, is freely rotatably disposed about inner  
15 shaft 330 and slidably disposed about inner shaft 330 within a range bounded by points  
16 334 and 337. In Figure 20f, the outrigger 324 is retracted, and outer shaft 333 is located  
17 at a position of origin along a z-axis parallel to the inner 330 and outer 333 shafts, such  
18 that the proximal end of the ring 320 is located at position 335. In Figure 20g, the  
19 outrigger 324 is extended, and outer shaft 333 is located at a position .250 in. (.64 cm.)  
20 from the origin of the z-axis parallel to the inner 330 and outer 333 shafts, such that the  
21 proximal end of the ring 320 is located at position 335'. The motion of the sliding of the  
22 outer shaft 333 about inner shaft 330 during marking is translated via the outer shaft 333,  
23 rotating portion 322 and ring 320 (including marking button 321 and marking point 326)

1 to a location along the scroll 317. Thus, as the user rotates outrigger 324 by rotation of  
2 rotating portion 322, the outrigger moves along the articular surface proximally or  
3 distally with respect to the inner shaft, and the displacement of the outrigger 324 along a  
4 z-axis parallel to the inner 330 and outer 333 shafts may be marked on the scroll 317 by  
5 depression of the button 323 at various points along the rotation of the outrigger 324.  
6 The tactile feedback portion 318 has a series of depressions 319 or other tactile feedback  
7 means, e.g. spring ball plungers which engage in indentations (not shown) in the inner  
8 shaft 330, spaced at 90 degrees from one another, so that when the rotational lock 323 is  
9 engaged as rotating portion 322 is being rotated, the user feels a "click" or other tactile  
10 feedback to indicate to the user the rotational location of the rotating portion 322 at 90  
11 degree intervals with respect to the handle 316, i.e., at 90 degrees, 180 degrees, 270  
12 degrees, and 0 (or 360) degrees, for purposes of marking at those points. It is further  
13 noted that the starting point for marking may or may not be selected independent of the  
14 90-degree rotational points, and that the rotating portion 322 may or may not be  
15 configured so that it is not tied to the 90-degree indexing until the scroll lock 323 is  
16 engaged.

17 As shown in Figures 20e, 20h and 20i, a keyed mating feature 331 may be  
18 disposed at the distal end of the inner shaft 330 with respect to the outrigger portion, for  
19 mating with a key feature 315 on the screw 10' (as shown in Figures 9c and 20i), so as to  
20 locate properly the starting point of the measurements taken with respect to the screw,  
21 and the scroll 317. Figure 20h illustrates a more detailed view of the distal end of the  
22 marking tool 210', with outer shaft 333, inner shaft 330 with keyed mating feature 331,  
23 and outrigger 324 with rounded end 338, which travels along the path of circle 339.

1 Figure 20i illustrates the measuring tool 210', with the keyed mating feature 331 inserted  
2 into the recessed portion 303 of the screw 10' at its fixation element 302.

3 Referring now to Figure 14a, data recorded during the mapping procedure  
4 described above can then be entered into a known parametric engineering design software  
5 or similar algorithm, as four values, 85a, 85b, 85c, and 85d, corresponding to the four  
6 measured points, 81a, 81b, 82a and 82b, with the origin 80 defining a reference plane.  
7 These four values 85a, 85b, 85c and 85d, are represented by line elements that are  
8 geometrically constrained to lie upon a circle 90, which represents the diameter of the  
9 measuring tool 70. These line elements are also constrained to lie within planes that are  
10 perpendicular to one another. Of course, more than four points may be taken and used to  
11 map the articular surface, e.g., 8 points; however, a minimum of four points should be  
12 taken, so that two intersecting datum curves may be defined for purposes of mapping.

13 Datum curves 86 and 87, representing the medial-lateral ("ML") and anterior-  
14 posterior ("AP") curves, are constructed by connecting the end points of the line elements  
15 81a and 81b, and 82a and 82b and the point of origin 80, which is common to both  
16 curves. These two datum curves 86 and 87 can be used to construct the articular or  
17 bottom surface 41 of the prosthetic implant 40. By sweeping datum curve 87 along a  
18 path defined by datum curve 86, a three dimensional surface is now defined.

19 By constructing this series of geometric relationships in a known parametric  
20 engineering model, patient-specific geometry can be input as values and the model  
21 algorithm can be run to reproduce the anatomic contours mapped in the patients within  
22 only a few moments. As a process, this generic model is the starting point for all patient  
23 treatments. Sterile pins, screws, and measuring devices that are all non-patient-specific

1 may be stocked in the hospital and ready to use whenever an appropriate defect is  
2 diagnosed. Patient-specific data may be transmitted from the surgeon to the fabricating  
3 facility via an interface to the Internet or other network. Data input into the interface may  
4 be read directly into the generic parametric model to produce a viewable and even  
5 mappable patient-specific parametric model within moments. Confirmation by the  
6 surgeon could initiate a work order for the production of the patient specific device.

7 Existing technology allows the parametric model to generate toolpaths and programming,  
8 e.g., to a CAD/CAM system comprising appropriate hardware and/or software coupled to  
9 appropriate data-driven tools, to fabricate the implant.

10 Defining two additional datum curves 88 and 89, at offset distances from datum  
11 curves 86 and 87, is performed to define the top or non-bearing surface 42 of the implant  
12 40. This top surface 42 should be closely matched to the bearing surface geometry to be  
13 implanted without having to remove an excessive quantity of bone from the chondral  
14 surface.

15 Referring to Figures 14c and 19c, implant geometry may be defined whereby the  
16 top or bone contacting surface 42 of the implant 40 exhibits an axial symmetry. The  
17 central axis AA passes through the point of origin 80 of the implant 40 and when the  
18 implant is positioned at the target site, aligns with the original reference axis 20A as  
19 defined by the guide pin 20 and fixation screw 10. The central axis AA can then be used  
20 to define the preparation tools so that the bone contacting surfaces 42 of the implant 40  
21 and the preparation tools can be matched in both configuration and dimension to create a  
22 mating fit between the surface of the prepared target site and the bone contacting surfaces  
23 42 of the implant. For example, if the preparation tools can be fabricated using some of

1 the same dimensions obtained during the articular surface mapping procedure, the  
2 implant geometry and corresponding preparation tool geometry can be mated and  
3 optimized so that a minimum vertical thickness of the implant as well as a minimum  
4 depth of bone removal is required. This may be advantageous in ensuring good long  
5 term clinical results with the implant, as poor quality of fit between bone surfaces and  
6 bone-contacting surfaces of traditional orthopedic prosthetic devices has been noted to  
7 contribute to early clinical failures.

8 For example, as shown in Figures 14c and 19c the top or bone contacting surface  
9 42 of the implant 40, a series of radial cuts 198 may create surfaces that increase  
10 resistance of the implant to rotational forces. These features may be located at the outer  
11 diameter 190 of the implant 40 to increase their effectiveness. Additional contact  
12 surfaces may also be created by one or more protrusions 195 located on the bottom 42 of  
13 the implant. Similarly, surface treatments known in the field of orthopedic devices, such  
14 as porous and/or osteoconductive coatings, may be utilized on surface 42.

15 As shown in Figure 19b, outer diameter 190 may include a slight outward taper or  
16 protrusion 197 along the diametrical surface to enhance load bearing or load transfer  
17 properties of the implant to surrounding bone. This feature may also increase the fixation  
18 strength of the implant. A fillet 199 (as shown in Figure 19a) that runs around the  
19 implant at the intersection of the diametrical surface 190 and the bearing surface 41 is  
20 also useful in providing a smooth transition between the host articular cartilage and the  
21 implant surface.

22 However, if a greater depth of implant is needed as a result of the defect  
23 appearance the offset curves 88 and 89 (as shown in Figure 14a) can be extended to

1 increase the overall thickness of the implant 40 or the offset curves may be eliminated  
2 entirely so that the contoured surface is backed by a revolved geometry that is  
3 symmetrical to reference axis 20A. Turning to Figure 19c, where the ML curve and AP  
4 curve (defined by the obtained measurements) are not axially symmetrical, the thickness  
5 of the implant 40 requires adjustment. At the same time, an unnecessarily thick implant  
6 requires a greater amount of bone to be removed at the target site. Therefore, the  
7 thickness of the implant may be determined by taking the largest obtained measurement  
8 and adding a minimal offset amount 208. (The implant is thinnest at the highest point on  
9 the ML curve.) This can be similarly accomplished by adjusting the angle  $\Delta$  (Figure 19a)  
10 of the bone-contacting surface 42 of the implant 40 and a corresponding angle of the  
11 preparation tool. This also allows for a correction of the implant geometry, to  
12 compensate for any non-perpendicular placement of the guide pin with respect to the  
13 articular surface.

14 With reference now to Figures 25 and 26, an exemplary algorithm consistent with  
15 the invention establishes the minimum thickness of an implant necessary to include all  
16 patient data points, receiving as input all of the points measured (typically, four) and  
17 identifying the largest value. One such exemplary algorithm is as follows (and as shown  
18 in Figures 25 and 26):

```
19     maxval= D6
20     if maxval < D11
21         maxval = D11
22     endif
23     if maxval < D14
24         maxval = D14
25     endif
```

1                   D684 = maxval + .045

2

3    In the foregoing exemplary algorithm, a first data point D6 is initially assigned as the  
4    maximum value (maxval). If...then type statements are used to compare other data  
5    points (D11 and D14) to maxval. If other data points are greater than maxval, the  
6    algorithm reassigns maxval to the new larger data point. LLMT represents the height of  
7    the lower limit plane along the z-axis, and ULMT represents the height of the upper limit  
8    plane along the z-axis. D684 is a dimension that controls the ULMT plane, which is  
9    established in the model as the upper surface of the implant. ULMT is positioned as  
10   maxval plus an additional arbitrary and/or fixed material offset (.045 in this case).

11                  Figures 5c and 5d illustrate an alternative embodiment of the implant 40', having  
12    a ML curve between data points 340 and 341 and an AP curve between data points 342  
13    and 343, with male-shaped mating component 304 and key-shaped portion 344 for  
14    engagement with a reciprocal key-shaped surface in the proximal extension of a fixation  
15    screw, protrusions 345 (creating contact surfaces on the top 346 of the implant 40'),  
16    radial cuts 347 located at the outer diameter 348 of the implant 40', and radius 349  
17    (which may be formed, e.g. using an abrasive wheel) around the intersection of the outer  
18    diameter at point 341 and the surface comprising the patient geometry.

19                  Referring to Figures 18a and 18b, bone cutting or scoring instrument 250 includes  
20    a handle (not shown), a cannulated shaft 111 that extends through the handle, and offset  
21    arm 140 housing adjustable blades 141. In the embodiment shown, individual cutting  
22    blades 141 are attached to offset arm 140 either fixedly or removably, e.g. via threaded  
23    portions 142, into threaded recesses 342 of the offset arm 140, although other attachment  
24    means may be used. With guide pin 20 advanced through shaft 113 positioned on the

1 reference axis 20A, a fixed distance from the rotational or references axis 20A to each of  
2 the cutting or scoring blades 141 is established. These lengths define the radii that are  
3 to be effected in the articular surface, as the scoring instrument 250 is rotated around the  
4 guide pin 20, corresponding to the protrusions 195 on the bone contacting surface 42 of  
5 the implant 40 creating a matching fit between the bone surfaces of the prepared target  
6 site and the bone contacting surfaces of the implant.

7 In an alternative embodiment, as shown in Figure 18c, cutting blades are arranged  
8 on carrier 145, configured so that it can be mounted within the slotted surface 114 of  
9 offset arm 112, depicted in Figure 17a. In another embodiment, as shown in Figure 18d,  
10 cutting blades 141 can be fixedly positioned on offset arm 140. Using the same  
11 dimensions obtained during articular surface mapping procedure, the cutting and scoring  
12 device 250 can be fabricated to prepare the articular surface to correspond to the implant  
13 geometry to optimize fit. In another alternative embodiment, as shown in Figure 18e, a  
14 bone cutting instrument 352 corresponds to the alternative embodiment of the implant 40'  
15 illustrated in Figures 5c and 5d. Instrument 352 has a handle (not shown), a cannulated  
16 shaft 353 that extends through the handle and through the cannulation 355, offset arm  
17 354 with blades 350 and 351 corresponding to the protrusions 345 on the bone contacting  
18 surface 42 of the implant 40 creating a matching fit between the bone surfaces of the  
19 prepared target site and the bone contacting surfaces 346 of the implant 40'.

20 As shown in Figure 14b, an angular dimension 95, relating some locating surface  
21 or feature on the hex-shaped cover 30 or on the fixation screw 10, to the four points 81a,  
22 81b, 82a and 82b, may also be captured at the time of the initial procedure to assist in  
23 orientation of the implant 40 to the fixation screw 10. Guide aperture 46 in implant 40 is

1 located off the reference axis 20A and may serve as the locating feature and/or as a suture  
2 passage way in the implantation procedure. Alternatively, a surface or feature created on  
3 the implant 40, may serve to reference or align to such locating surface on the hex-shaped  
4 cover 30 or the fixation screw 10.

5 Additional data can be taken at the time of the initial procedure, e.g., for  
6 fabricating a non-circular implant. Additional data curves can also be defined by  
7 measuring the offsets from the reference axis 20A and determining diameters at these  
8 offsets. The final implant geometry, although measured using circular techniques, need  
9 not be circular.

10 Referring to Figures 10a and 10b, following fabrication of the implant 40, a  
11 second procedure is performed. If a cover 30 (or plug) is in place, it is removed,  
12 exposing proximal extension 14 (or recess) or some other precision taper or engagement  
13 surface located at the proximal end 17 of the fixation screw 10 to which the implant 40 is  
14 to be affixed. A pin having a distally mounted element or barb 5 is placed through  
15 through hole 16 running through the central lumen of the fixation screw 10 so that the  
16 distally mounted element 5 is secured into the screw. The distally mounted element 5  
17 carries one or more suture strands 85 that now trail from the fixation screw 10.  
18 Alternatively, a pin, braided cable, or flexible wire may also be used. However, sutures  
19 may make passing the implant 40 through the incision 200 and subsequent handling  
20 easier.

21 Turning to Figures 11a and 11b, the sutures 85 are then threaded through guide  
22 aperture 46 of the implant 40 and a knot or bead 49 may be created proximal to the  
23 implant, so that tensing one of the free running sutures 85 helps to advance the implant

1 40 toward the proximal extension 14 (or recess) of the fixation screw 10. Alternatively,  
2 the suture strands 85 can be passed through the central lumen or shaft of a driving rod or  
3 other instrument to aid in seating the implant 40, and positioned in the fixation screw 10  
4 thereafter.

5 If necessary, the arthroscopic wound 200 is expanded slightly in either a vertical  
6 or horizontal direction, so that the implant 40 may be passed through. A polymeric  
7 sleeve (not shown) positioned over the implant may prove helpful in passing the implant  
8 through the incision. As shown in Figure 11b, based on the size of the implant 40,  
9 anatomy of the knee 50, and retraction of the knee, it may be necessary to position the  
10 implant in the interchondular notch 77 as a staging area prior to final placement. By  
11 continuing to manipulate and tension the suture strands 85, the implant 40 can be brought  
12 coaxial to the proximal extension 14 of the fixation screw 10.

1        As shown in Figures 15c and 15d, alternatively, driver 130 includes handle 110, a  
2        cannulated shaft 111 that extends through the handle and a cannulated seat portion 131  
3        attached to the end of the shaft. Tether element 135, which may comprise sutures or  
4        wire, is passed through driver 130 and is threaded through implant 40 through guide  
5        aperture 46, connecting the implant to the driver toward seat portion 131. The implant  
6        40 and the driver 130 are then inserted arthroscopically through incision 200 to the target  
7        site. By tensioning tether element 135 at the end 136 of handle 110, the implant 40 is  
8        drawn back into seat portion 131 of driver 130. By maintaining tension on tether element  
9        135, the implant 40 can then be controllably delivered to the prepared target site. At  
10        least the inner surface of seat portion 131 comprises a material that can be impacted to  
11        seat the implant 40 without damaging the implant surface.

12        Referring to Figure 12, once coaxial, the implant 40 can be aligned via  
13        engagement of the proximal extension 14 on fixation screw 10 and precisions taper 44 on  
14        the bottom surface 42 of the implant and any locating feature, and driven into place with  
15        a plastic driving rod 91 and mallet 95. A protrusion 92 of high strength material mounted  
16        at the distal tip 93 of the driving rod 91 may be necessary to ensure that the rod stays  
17        centered on the implant 40 during driving.

18        Finally, as shown in Figure 13, through guide aperture 46 on the upper surface 41  
19        of the implant 40, bone cement 300 may be injected to enhance the contact surface  
20        between the implant 40 and the subchondral bone 100. Vents, such as milled slots 13 in  
21        the fixation screw 10, and in the walls of the implant central protrusion may be desirable  
22        to facilitate the flow of such materials.

1        Alternatively, guide aperture 46 in the implant 40 may be altogether eliminated by  
2        using an alternative implant delivery system, as shown in Figures 19d through 19i,  
3        corresponding to an implant similar to that shown in Figures 5c and 5d. The alternative  
4        system comprises the implant 40" and a washer 361 for holding a suture 363, the washer  
5        361 being adapted to fit into a taper lock ring 360. The ring 360 has a taper lock portion  
6        362 having a series of notches 365 along its perimeter, creating flaps 372 that permit the  
7        taper lock portion 362 to flex somewhat. The taper lock portion 362 has a diameter  
8        gradually tapering from the middle to the proximal end 364 of the ring. The taper lock  
9        ring 360 may also have an alignment notch 386 or similar feature for properly aligning  
10      the taper lock ring 360 with respect to key-shaped portion 344 of the implant 40", which  
11      is to engage with a reciprocal key-shaped surface in the proximal extension of a fixation  
12      screw, so as to seat properly the implant rotationally with respect to the defect site when  
13      it is later seated thereon. A washer 361 is disposed between the ring 360 and the implant  
14      40" and has two apertures 366 disposed in a recessed area 367 in the center of the  
15      washer. The suture 363 is threaded through the two apertures 366 to form a suture loop  
16      368, which remains in the recessed area when the ends of the suture 363 are pulled, so as  
17      to keep the suture loop 368 below the top surface 369 of the washer 361. The implant  
18      40" has a diameter at its center portion 370 that is approximately equal to the inner  
19      diameter of the ring 360 at its taper lock portion 362. Thus, when tension is applied to  
20      the ends of the suture 363, the taper lock portion 362 of the ring 360 may flex outward to  
21      receive slidably therein the implant 40" and washer 361, which subsequently lock into  
22      the taper lock portion 362 of the ring, once the center portion 370 of the sides of the  
23      implant 40" is seated within the proximal end 364 of the ring by friction fit, as shown in

1     Figure 19e. It is noted that the center portion 370 of the sides of the implant 40" to be of  
2     a width permitting the implant and washer to travel slidably within the ring 360 to some  
3     degree.

4             As shown in Figure 19f, a hex nut 373 may be integrally formed in the center of  
5     the washer 361 on its bottom side 374, for mating with an appropriately configured tool  
6     for seating the implant 40". As Figure 19f illustrates, the implant 40", along with  
7     washer 361, ring 360, and sutures 363, is pushed through the incision 200 at the defect  
8     site. Next, as shown in Figures 19g – 19i, illustrative of successive steps in the process of  
9     seating the implant, a seating tool 380 may be used to seat the implant. Seating tool 380  
10    comprises a shaft 385, a handle 381 (which may have a through hole 382, if the same  
11    handle and/or shaft is used with interchangeable tips for performing various functions,  
12    although a through hole 382 is not integral to seating the implant), and tip 383 suitably  
13    configured to drive hex nut 373 (or other mating feature) and having an aperture 384  
14    through which the ends of the suture 363 may be threaded. Once the tip 383 of the tool  
15    380 is introduced into the incision 200, the sutures 363 may be used as a guide for seating  
16    the tip 383 of the tool 380 onto the hex nut 373, which may be accomplished by  
17    alternately pulling on each end of the suture 363 to toggle the tip 383 of the tool 380 back  
18    and forth. Once the tip 383 of the tool 380 is seated onto the hex nut 373, the tool 380  
19    may be rotated in either direction to seat the implant assembly properly (comprising  
20    implant 40", taper lock ring 360, and washer 361) at the defect site. This may be  
21    effected by rotating tool 380 until alignment notch 386 and corresponding key-shaped  
22    portion 344 of the implant 40" are aligned with the corresponding reciprocal key-shaped  
23    surface in the proximal extension of the fixation screw, whereby the implant should slide

1 into place, thereby properly seating the implant rotationally with respect to the defect site.  
2 As shown in Figure 12 with respect to the prior described embodiment, once properly  
3 seated, the implant 40" can be driven into place with a plastic driving rod 91 and mallet  
4 95, and as shown in Figure 13 with respect to the prior described embodiment, bone  
5 cement 300 may also be placed prior to the final seating of the implant 40" to enhance  
6 the contact surface between the implant 40" and the subchondral bone 100. It should be  
7 understood that the taper lock ring 360, washer 361, and sutures 363 described with  
8 respect to this embodiment allow the implant to be noncannulated but still easily handled.  
9 These elements are not required to be constructed as illustrated herein, and may be  
10 replaced by adhesive components, suction components, or other components serving the  
11 same function.

12 As Figures 21 and 22 illustrate, a unitary (one-piece) implant 400 may also be  
13 constructed, thereby obviating the need for a fixation screw, taper lock ring, washer, and  
14 suture. In this embodiment, implant 400 has key-shaped portion 401 for engagement  
15 with a reciprocal key-shaped surface 411 in an aperture 412 at the defect site 410, a  
16 plurality of barbs 402 (or other mating features, e.g., one or more threads, ribs, fins,  
17 milled slots, tapered distal features, features to prevent rotational movement of the  
18 implant, or features to increase friction between the implant and the aperture at the defect  
19 site) for producing outward tension within the aperture 412 at the defect site 410 and for  
20 increasing the contact surface area of the implant 400 with respect to the aperture 412 at  
21 the defect site 410. In this embodiment, an aperture 412 having a key-shaped surface 411  
22 or other feature for mating with the implant is created directly in the defect site 410, by  
23 boring, abrasion, or other techniques for forming an appropriately shaped aperture in the

1 chondral bone 410 for receiving an implant 400 having a corresponding key-shaped or  
2 other mating feature 401. It should also be recognized that, in this or other embodiments,  
3 the fixation screw could be replaced with a tensioned member attachment, e.g., anchored  
4 to the distal femoral cortex. Alternatively, the fixation screw could be configured as a  
5 guide wire, only to define the axis AA corresponding to an axis about the point of origin  
6 in the implant to be used (as shown in Figures 14c and 19c), but not to provide  
7 mechanical anchoring to or for the implant.

8 Figure 23 illustrates other alternative embodiments for an implant consistent with  
9 the invention, showing a perspective view of the components of an exemplary composite  
10 implant, in one embodiment of the present invention. As shown, implant 500 comprises  
11 top 501 and bottom 502 portions. Top portion 501 has a bottom surface 503 which may  
12 be glued, welded, bonded, or otherwise attached to top surface 504 of bottom portion  
13 502, while bottom surface 505 of bottom portion 502 comprises the patient geometry and  
14 is the load-bearing surface of the implant, as set forth hereinabove. Top 504 and bottom  
15 505 surfaces of the bottom portion 502 may comprise, in whole or in part, bioengineered  
16 material, while top portion 501 may comprise a material such as titanium. In such a  
17 configuration, top portion 501 may be fabricated and/or manufactured (e.g. in large  
18 quantities) as a universal, generic, standard supply item for medical practitioners, which  
19 merely needs to be attached to a custom-machined bottom portion 502 comprising the  
20 patient-specific geometry. Surfaces 503 and 504 may be flat or may comprise other  
21 mating features, shapes or configurations.

22 Further composite implant embodiments are illustrated in Figure 24, wherein  
23 implant 600 comprises the patient-specific geometry 603 and a uniform thickness

1 material bottom portion 602 comprising the bottom or bearing surface 606. The bottom  
2 surface 603 of top portion 601 mates with the top surface 604 of bottom portion 602, and  
3 surfaces 603 and 604 may be flat or may comprise other mating features, shapes or  
4 configurations. Lip 605 of bottom portion 602 has an inside diameter substantially the  
5 same as the outside diameter of top portion 601, so that top portion 601 fits slidably into  
6 bottom portion 602, whereby the two portions 601 and 602 may be glued, welded,  
7 bonded, or otherwise attached to one another. Bottom surface 606, being of uniform  
8 thickness, reflects the patient-specific geometry which surface 603 comprises and is the  
9 load-bearing surface of the implant.

10 Other materials from which an implant consistent with the invention may be  
11 constructed, in whole or in part, include ceramic, e.g. aluminum oxide or zirconium  
12 oxide; metal and metal alloys, e.g. Co-Cr-W-Ni, Co-Cr-M, CoCr alloys, CoCr  
13 Molybdenum alloys, Cr-Ni-Mn alloys, powder metal alloys, 316L stainless steel, Ti 6Al  
14 – 4V ELI; polymers, e.g., polyurethane, polyethylene (wear resistant and cross-linked),  
15 thermoplastic elastomers; biomaterials, e.g. polycaprolactone; and diffusion hardened  
16 materials, e.g. Ti-13-13, Zirconium and Niobium. Coatings used may include, e.g.,  
17 porous coating systems on bone-contacting surfaces, hydrophilic coatings on load-  
18 bearing surfaces, hydroxyapatite coatings on bone-contacting surfaces, and tri-calcium  
19 phosphate on bone-contacting surfaces. Additionally, components of the invention may  
20 be molded or cast, hand-fabricated, or machined.

21 Alternatively, measurement methods may be utilized whereby radius  
22 measurements are taken with respect to an axis AA corresponding to an axis about the  
23 point of origin in the implant to be used (as shown in Figures 14c and 19c). The

1 technique is used in reverse, whereby aiming devices are used to place axis AA with  
2 respect to prefabricated generic-geometry implants.

3 It is noted that, although the invention is herein described as utilizing a single  
4 reference axis, multiple reference axes may be used for measuring, mapping, or cutting a  
5 single defect or an articular surface having multiple defects, as well as for fabricating a  
6 single implant, or multiple implants for a single articular surface, consistent with the  
7 invention. In other embodiments, methods for mapping the defect and/or articular  
8 surface other than those described hereinabove are possible, e.g., MRI or CT scanning,  
9 fluoroscopy, ultrasound, bone density, other stereotactic systems, nuclear medicine, or  
10 other sound or light wave-based imaging methods.

11 It is further noted that, although the invention is described herein as utilizing the  
12 specific geometry of a patient's articular surface to fabricate an implant for that patient, it  
13 is contemplated that data from a plurality of patients may be analyzed statistically and  
14 utilized in fabricating and/or manufacturing (e.g. in large quantities) one or more  
15 universal, generic, or standard supply item type implants for medical practitioners to use  
16 in a procedure consistent with the invention. For such implants, as well as for patient-  
17 specific implants as described herein, pre- or post-implantation trimming may be required  
18 to correct for minor variations that may occur as between the implant and the subchondral  
19 bone (or other articular surface).

20 It should be understood that, although the various tools described hereinabove,  
21 e.g., for measuring, cutting, and seating, are described as separate devices, a single  
22 handle, shaft and/or instrument may be configured to serve as a universal mounting tool  
23 for a series of devices for performing various functions consistent with the invention.

## Generic Bone Resurface Implant, Cutting Tool, and Procedure

2 Figures 27a-48 depict another exemplary embodiment of the present invention. In  
3 this embodiment a generic bone implant (or set of standardized implants) is created (or  
4 selected) based on developing an axis normal to the surface and collecting only one data  
5 point. In the above-described embodiments, a non-normal axis was utilized, and four  
6 data points were required to develop ML and AP curves. Further, a generic cutting tool is  
7 used to cut the bone at this site to a point where a generic implant can be used. Several  
8 improved tools relating to the procedure for using such an implant (as well as for using  
9 implants as described hereinabove) are further described in this section and illustrated in  
10 the corresponding figures.

11       Figure 27a depicts an exemplary drill guide device 700 according to this  
12       exemplary embodiment. The guide 700 includes a contact surface 702 of known  
13       diameter  $d$  on the distal end 708 of the guide, where diameter  $d$  is generally the width of  
14       the widest portion of the site of the lesion. The distal end 708 of the guide is generally a  
15       hollowed-out toroidal structure attached to a handle 706. A central lumen 704 runs the  
16       length of the guide from the attachment point of the distal end 708 to the handle 706, and  
17       through the handle 706. The guide device may be constructed in a number of other ways,  
18       including, e.g., a distal end 708 comprising a transparent material, e.g., polycarbonate or  
19       another clear plastic. For example, as shown in Figure 27b, a guide device 700' may  
20       comprise a distal end 708' (which could comprise either an opaque or a transparent  
21       material) having a plurality of cutaway areas 743 to improve visibility and the accuracy  
22       of drill location with respect to the site of a lesion. The guide device may also comprise a  
23       tripod-like construction, or other construction comprising fins, or projections. It should

1 be noted that, instead of a central lumen being used to locate the working axis, a  
2 cylindrical bore located at some distal location of the guide may serve to create a working  
3 axis that is not necessarily coaxial to the handle or connecting shaft of the instrument.

4 Referring now to Figures 28a and 28b, the present embodiment operates on the  
5 assumption that to a first approximation an anatomical model of some articular surfaces  
6 (e.g., knee, hip, etc.) can be assumed to be locally spherical. In other words, as shown in  
7 Figures 28a and 28b, the AP plane and ML plane, respectively, are depicted, wherein  
8 each corresponds to a model of the articular surface of a femoral region. These figures  
9 break up these cross-sections into a plurality of radii of arcs defining the articular surface,  
10 i.e.,  $R_1-R_4$  in the AP plane, and  $R_5-R_7$  in the ML plane. In this embodiment, the inventors  
11 herein have found that surfaces in some regions can be assumed to be substantially  
12 locally spherical. Thus, for example, the present embodiment assumes that  $R_3$   
13 approximately equals  $R_6$  (i.e.,  $R_3$  is within 50% of  $R_6$ ). Under these assumptions, a  
14 normal axis can easily be developed. Once developed, one data point then needs to be  
15 defined to obtain the relevant geometry of an implant, as will be described below. If  $R_3$   
16 is not within 50% of  $R_6$ , an alternative method for developing an axis normal to the  
17 surface of the lesion site, as described hereinbelow with reference to Figures 49-53, may  
18 be used.

19 Figures 29-34 depict the use of the drill guide, the generic implant, and  
20 procedures therefor, according to this exemplary embodiment. In Figure 29, the drill  
21 guide 700 is brought up to a lesion site 712 of the articular surface 710. The guide 700 is  
22 positioned so that the distal end 702 covers the lesion site 712, such that the contact  
23 surface of the distal end 702 makes contact at a plurality of points around the lesion site

1 712 on the articular surface 710. As shown in Figure 30, with slight pressure the guide  
2 700 becomes stable and fixed on the articular surface 710. Once seated in position, a  
3 guide pin 714 is driven through the central lumen of the guide to create a working axis  
4 that is generally normal to the articular surface 710 at the point of contact of the guide  
5 pin. As Figure 31 illustrates, a standard bore drill (not shown) can be placed over the  
6 guide pin 714 to create a pilot hole 716 for the screw (not shown).

7 With reference now to Figure 32, as with the previous embodiments described  
8 above, a screw 720 is driven into the pilot hole 716. A cap 722 having a male component  
9 719 adapted to mate with the female taper 718 of the screw 720 is placed on the screw  
10 720. The screw is driven to the appropriate depth, such that the top surface of the cap  
11 722 is substantially aligned with the articular surface 710, within the lesion site 712,  
12 thereby ensuring congruency of the implant to the joint. Turning now to Figure 33, the  
13 cap 722 is removed, and a rod 730 having a mating taper 731 on its distal tip is inserted  
14 into the screw 720. The guide 700 is positioned over the rod 730 so that the distal end  
15 702 covers the lesion once again. As illustrated in Figure 34, since the length of the rod  
16 730 and the length of the guide 700 are known, a measurement of the exposed end length  
17 of the rod ( $l$ ) may be taken. This will provide the information needed with respect to the  
18 implant geometry, by indicating the distance between the seating depth in the screw and  
19 the tangent point of the implant surface. As shown in Figure 35, since the axis,  $z$ , is  
20 defined (by the drill guide) as normal to the surface of the implant at a plurality of points,  
21 all dimensions defining the AP and ML curves may be assumed to be equal, such that  
22 only one dimension,  $l$ , is left to define the implant geometry. Variations from knee to  
23 knee and within a knee may be reflected in changes in  $l$ . For example, the implant 736 of

1     Figure 36 may be compared to the implant 737 of Figure 37. For implant 736 of Figure  
2     36, the value of  $l_1$  represents a relatively “flat” region on the articular cartilage, where the  
3     radius of the arc  $R_{AC1}$  is a relatively large number. However, for implant 737 of Figure  
4     37, the value of  $l_2$  represents a more curved region on the articular cartilage, where the  
5     radius of the arc  $R_{AC2}$  is a smaller number than  $R_{AC1}$ . As indicated by clinical data, there  
6     is a range of values for  $l$  that suggests 5 to 6 values of  $l$  that will fit a majority of people.  
7     Thus, generic, off-the-shelf sized implants may be made. A single procedure technique  
8     involving establishing the normal axis, measuring  $l$ , and selecting the appropriate size  
9     implant is therefore feasible.

10           As illustrated in Figure 38, an exemplary cutting or reaming tool 740 (e.g., as  
11     described hereinabove with respect to Figures 15b and 16) is used to prepare the lesion  
12     site 712 to receive the implant (not shown). The cutting or reaming tool 740 may be  
13     configured so that, when coupled to the axis defined by the guide pin, it can be used for  
14     cutting operations. The tool 740 may have a cannulated shaft and a distal offset arm  
15     having a cutting or blade surface (not shown) having a radius corresponding to the radius  
16     of the implant to be used, such that the articular cartilage may be circumscribed by  
17     rotation of the tool 740 for cleanly cutting the surrounding articular cartilage in  
18     preparation for receiving the implant. The tool 740 may be configured so that, when  
19     coupled to the axis defined by the guide pin, it can be used for cutting operations. The  
20     proximal face of the screw 720 may serve as a depth stop for the proximal portion of the  
21     tool 740, thereby defining a cutting/reaming depth corresponding to the thickness of the  
22     implant,  $l$ .

1        Those skilled in the art will recognize that the cutting tool may be motorized in  
2        certain embodiments, and/or alternatively, as illustrated in Figure 39, an exemplary  
3        cutting tool 744 may comprise a cannulated shaft 749, a circular blade portion 745 having  
4        a leading edge 746 comprising a blade surface turned on the distal-most portion. Such a  
5        tool 744 may further comprise a handle portion 747 and may be adapted to be turned by  
6        hand by the operator of the tool by means of rotating the handle 747, or alternatively,  
7        may be motorized in certain embodiments.

8        Figure 40 illustrates an exemplary cleaning tool 770 for cleaning the female taper  
9        (not shown) of the screw 720 prior to delivery of the implant. The distal end 771 of an  
10       exemplary cleaning tool 770 comprises a semi-rigid material formed into a shape adapted  
11       to enter into the female taper of the screw 720 and be manipulated by the operator of the  
12       tool, to remove tissue or other debris therefrom, thereby ensuring a good mate of the  
13       female taper 720 of the screw and the male taper of the implant to be delivered (not  
14       shown).

15       Figures 41-43 illustrate an exemplary suction tool 760 for holding the implant by  
16       means of a suction force and delivering it to the lesion site, as well as the steps of an  
17       exemplary procedure for using the suction tool 760 to deliver an implant. As illustrated  
18       in Figure 41, an exemplary suction tool 760 comprises an elastomeric suction tip 761 at  
19       its distal portion 767, a proximal surface 768, an inlet 762 for mating with a suction tube  
20       763 connected either to a hospital wall suction supply 764 or other suction system, and a  
21       switch or valve 765 for controlling the suction force. As Figure 42 illustrates, when the  
22       suction force at the elastomeric suction tip 761 is activated by the switch or valve 765,  
23       the implant 742 is held in place, and thus, the suction tool 760 may be used to hold the

1 implant prior to, and during, the delivery thereof. As shown in the cross-sectional view  
2 of Figure 43, the distal portion 767 of an exemplary suction tool 760 may comprise a  
3 rigid tip 766 (which may comprise, e.g., plastic material) disposed within the elastomeric  
4 suction tip 761. Force may be applied to the rigid tip 766 (e.g., by striking or pressing on  
5 the proximal surface 768 of the tool 760) in order to seat the implant 742 within the  
6 lesion site, once the male taper 769 of the implant 742 and its corresponding mating  
7 component(s) 778 are properly aligned with the female taper of the screw (not shown)  
8 and its corresponding mating component(s). Since the suction tip 761 is elastomeric  
9 (e.g., rubber), upon application of such force, the material will compress, allowing impact  
10 to be transferred to the implant 742 for purposes of seating it. It is noted that, in addition  
11 to its utility in delivering an implant, a suction tool 760 as described herein (or a suction  
12 tool similar thereto) might also be used at some point during the process of removing an  
13 implant (e.g., in the event the implant is not fully seated).

14 Figure 44 illustrates an exemplary implant 742 driven into the lesion site 712 of  
15 the articular surface 710 once the site 712 has been sufficiently reamed or cut.

16 Figure 45 illustrates an exemplary implant removal or revision tool 750  
17 comprising a shaft portion 751 and a distal portion 753, and Figure 46 is a cross-sectional  
18 view illustrating the exemplary tool 750 with a removed implant 742 being held in place  
19 therein. As shown, the distal portion 753 of the tool 750 may comprise an approximately  
20 cylindrical structure with a circular blade portion 752 having a leading edge 758  
21 comprising a blade surface turned on the distal-most portion and a lip portion 755  
22 disposed proximally with respect to the leading edge 758. A plurality of slits 754 parallel  
23 to the longitudinal central axis of the distal portion 753 are disposed along the length of

1 the cylindrical structure, so as to permit sufficient outward expansion of the distal portion  
2 753 to accommodate the top edge of the implant 742 therein. Thus, when the distal  
3 portion 753 of the tool 750 is forced onto an implant 742 to be removed, and driven down  
4 over the implant 742, the distal portion 753 will snap/lock into place once the lip portion  
5 755 of the distal portion 753 of the tool 750 passes the top edge of the implant 742 being  
6 removed, thereby holding the implant 742 in place within the distal portion 753 of the  
7 tool 750, as shown in Figure 46. At this point, a device such as a slap-hammer or slide  
8 hammer (not shown) may be used to unseat the implant 742. An exemplary such device  
9 may comprise a shaft having a weight slidably disposed thereon, wherein one end of the  
10 shaft is connected to the proximal end (not shown) of the tool 750 and the other end of  
11 the shaft comprises a stop for preventing the weight from moving off the shaft, and  
12 wherein the weight is propelled away from its connection point with the proximal end of  
13 the tool 750, such that it stops abruptly at the stop and exerts a pulling force on the  
14 implant.

15 Alternative Embodiment of Screw

16 Figures 47 and 48 illustrate an exemplary alternatively-keyed embodiment of the  
17 screw 720' (c.f., key feature 315 of screw 10', as shown in Figure 9c) and the exemplary  
18 alternatively-keyed implant 742' to which it is adapted to mate. As shown, the male  
19 taper 769' of the implant 742' is coupled at its distal end to an offset mating feature 778'  
20 for mating with a corresponding offset mating feature 779 of the screw 720'. The mating  
21 feature 778' of the implant 742' comprises a generally cylindrical structure (and may  
22 further comprise a rounded or chamfered distal end portion 777' and/or other geometric  
23 features, i.e., recesses and/or protrusions) and is both offset from the central longitudinal

1 axis of, and diametrically smaller than, the male taper 769' of the implant 742'. As  
2 Figure 48 illustrates, a generally cylindrical recessed mating feature 779 (or similar  
3 mating recess(es) and/or protrusion(s), e.g., a rounded or chamfered distal end portion  
4 780) corresponding to the offset distal mating feature 778' of the implant 742' is disposed  
5 within the innermost portion of the female taper 718' of the implant 742', and offset from  
6 the central longitudinal axis of the female taper 718'. The female mating feature 779 of  
7 the screw is provided to mate with the offset male distal mating feature 778' of the  
8 implant 742', so as to seat the taper 769' of the implant 742' at a fixed location within the  
9 screw 720', thereby preventing rotation of the implant 742' with respect to the screw  
10 720'. Along with the mating features 778', 779, the taper structures provided may serve  
11 to prevent movement of the implant 742' with respect to the screw 720' in all directions.  
12 A screw 720' consistent with the present invention may comprise a titanium alloy, e.g., a  
13 316L stainless steel alloy or a cobalt-chrome alloy.

14 Alternative Method for Developing Axis Normal to Lesion Site Surface

15 Figures 49-53 illustrate an alternative method for developing an axis normal to the  
16 surface of the lesion site using a biaxial measuring tool. This method has particular  
17 utility for lesion sites where the radii of arcs defining the articular surface,  $R_{ML}$  and  $R_{AP}$ ,  
18 are different, i.e., the region is not locally spherical. (This would be the case, e.g., if  $R_3$  is  
19 not within 50% of  $R_6$ , as illustrated in Figures 29a and 29b and described hereinabove.)  
20 To develop an axis normal to the surface, a biaxial measuring tool 800 is provided. The  
21 tool 800 comprises an outer shaft 805 coupled fixedly to an outer component 801 having  
22 a set of arms 803, and an inner shaft 806 slidably disposed within the outer shaft 805,  
23 wherein the inner shaft is coupled fixedly to an inner component 802 having a set of arms

1 804. The arms 803, 804 of the outer 801 and inner 802 components may take several  
2 forms, and one exemplary form for the arms 803, 804 is illustrated in Figures 49-53,  
3 wherein the distal portion of each arm 803, 804 tapers outward and connects to one of  
4 four contact portions 808. The contact portions 808 may be, e.g., as shown, one of four  
5 arcuate sections of a generally toroidal member (which may be solid or hollow) having a  
6 generally circular cross-section. (The lengths of the arcuate sections do not necessarily  
7 need to be equal to one another, e.g., as illustrated in the exemplary contact portions 808  
8 of Figures 49-53, the arcuate lengths of the contact portions 808 corresponding to the  
9 inner component 802 are shorter than those contact portions 808 corresponding to the  
10 outer component 801.) The inner shaft 806 may be biased forward so as to tend to extend  
11 from the outer shaft 805, or may alternatively be advanced manually without spring bias.  
12 The inner component 802 is slid proximally or distally with respect to the outer  
13 component 801, until all of the contact portions 808 make contact with the articular  
14 surface (not shown). In this manner, the articular surface curvatures may be separated  
15 into AP elements and ML elements, such that four separate contact points may be  
16 extrapolated from the four contact portions 808, based on the relative positions of the  
17 inner 802 and outer 801 components, and an axis normal to the surface of the lesion site  
18 may be defined. The shaft of the tool 800 may be cannulated (not shown), so as to allow  
19 a guide pin or wire (or a boring tool) to pass therethrough and into the articular surface,  
20 as described hereinabove with respect to Figures 27a to 31. As shown in Figure 53, if the  
21 inner 802 and outer 801 components are aligned such that the four contact portions 808  
22 meet to form a complete toroidal member or ring, the articular surface must be locally

1 spherical, i.e.,  $R_{ML}$  and  $R_{AP}$  (as shown in Figure 49) are equal, and it is therefore not  
2 necessary to use the biaxial tool 800.

3 It should be noted that, alternatively, contact surfaces may be constructed of some  
4 pliable, or malleable material(s) so that independently moving rigid mechanical members  
5 are not necessary. As long as the contact surfaces provide a normalizing force to some  
6 central shaft when the contact surfaces are applied to the articular surface, a normal axis  
7 could be defined.

8 In another embodiment, this biaxial guide could be replaced by a series of sized  
9 "trials" or gauges of predefined surfaces of varying dimensions, which are simply pressed  
10 onto the articular surface to visually determine an appropriate fit. These gauges may  
11 resemble an implant, as described herein, without any features (e.g., fixation element or  
12 screw) on the underside, and may contain a handling tab or other element for holding the  
13 gauge. The contact surfaces of these gauges may have a circular cross section, an ovular  
14 cross section, or another cross-section comprising a plurality of points to surround a  
15 defect in an articular surface, and the plurality of points may or may not lie in the same  
16 plane. Although they may be less precise or less accurate than other measuring methods  
17 described herein, it is contemplated that implant selection could be made directly from  
18 these gauges.

19 Digital Measuring System

20 Figures 54-61 illustrate an exemplary digital measuring system consistent with the  
21 present invention. As shown, the system 810 comprises a base unit 811 coupled to the  
22 handpiece 812 via a cable 813. As described further hereinbelow, the base unit 811 may  
23 comprise a tear strip 814 in or on the chassis for detaching a printed paper tape

1 comprising measurement data. Such a system may reduce or eliminate potential for  
2 surgical or other human error with respect to the implementation of the present invention.

3       Figure 55 is an exploded view of an exemplary handpiece 812 in a digital system  
4 consistent with the present invention. The linear measuring elements of the handpiece  
5 812 are nested concentrically and coaxially to the rotary measuring elements, so that  
6 when the probe assembly 818 is translated and rotated with respect to the main body 822  
7 of the handpiece, the  $\theta$  and  $z$  dimensions are simultaneously recorded. The handpiece 812  
8 comprises a main body 822 containing a linear reading head 813 coupled to a linear  
9 reader 814, a linear index strip 815, a rotary reading head 821 coupled to a rotary reader  
10 816, and a rotary index strip 817. The probe assembly 818 comprises a contact tip 819  
11 coupled to an inner shaft 820 running along the length of the handpiece 813 disposed  
12 within the main body 822. The shaft 820 comprises a mating feature 834 at its distal end  
13 that is keyed to fit in the mating feature of an implanted screw, such that the shaft 820  
14 provides a rotational axis. The shaft 820 is rigidly connected to the main body 822 of the  
15 handpiece 812 via a nut 823 at its rear. The handpiece 813 is coupled to, and transfers  
16 motion both rotationally and axially from, the contact tip 819 via the shaft 820. In this  
17 manner, the linear 815 and rotary 817 strips, which may comprise, e.g., mylar polyester  
18 film having thereon a very fine printed pattern, pass through the linear 813 and rotary 821  
19 reading heads, respectively, such that the heads 813, 821 read the pattern on the strips  
20 815, 817 and output data representing the rotational and axial travel of the contact tip  
21 819.

22       Exemplary strips and heads may include those manufactured by U.S. Digital<sup>TM</sup>  
23 Corporation of Vancouver, Washington, USA. Figure 55a is a cutaway view illustrating

1 an exemplary printed linear index strip 815 passing through an exemplary linear head 813  
2 for reading, and Figure 55b is a cutaway view illustrating two alternative exemplary  
3 printed rotary index strips 817, 817' of varying sizes passing through an exemplary rotary  
4 head 821 for reading. Figure 55c illustrates an exemplary linear index strip 815  
5 comprising concentric "bullseye" circles 830, reference lines 831, a text area 832, and a  
6 pattern area 833. Figure 55d illustrates an exemplary rotary index strip 817 comprising  
7 an opaque area 823, index areas 824, a pattern area 825, a text area 826, crosshairs 827,  
8 concentric "bullseye" circles 828 and a central aperture 829.

9       Turning now to Figures 56a and 56b, a rotational groove 840 and a linear groove  
10 841 are provided on the handpiece 812, such that the probe assembly 818 may slide onto  
11 the shaft 820 of the handpiece 812 and snap into the linear 841 and rotational 840  
12 grooves.

13       Figures 57 and 58 illustrate top and side views, respectively, of the assembled  
14 exemplary handpiece 812.

15       Figures 59 and 60 illustrate top and side cross-sectional views, respectively, of the  
16 assembled exemplary handpiece 812.

17       Figure 61 illustrates a cutaway view of an exemplary base unit 811 in an  
18 exemplary digital measuring system consistent with the present invention. The base unit  
19 811 comprises a power supply 850 (the system may be battery or AC-line powered), a  
20 paper roll 851, a thermal printer 852, a feed loop dowel 853 for threading the paper roll  
21 851 into the thermal printer 852, a set of controls or buttons 854, and one or more  
22 displays 855 (e.g., LED/LCD). The base unit 811 further comprises appropriate  
23 hardware and/or software to compare measured values to known values, as well as to

1 compare sweeps to one another to ensure procedural accuracy. Further, the displays 855  
2 and/or paper printouts from the thermal printer 852 may be adapted to display to the user,  
3 based on measured data, the ideal size of the generic implant to use. If a custom implant  
4 is required, a printout of the data set may be generated using the printer 852. The base  
5 unit 811 may further comprise other means of recording data (not shown), e.g., floppy  
6 disk, hard disk, memory/flash card, etc., and may further comprise appropriate hardware  
7 to provide output signals (e.g., via RS-232, USB, etc.) to external hardware. Instead of  
8 the strips, heads, and other recording elements described in the exemplary digital system  
9 hereinabove, other digital measurement methods may be used, including reflective light  
10 or sound methods, and percutaneous methods (e.g., using a hypodermic needle in  
11 conjunction with an MRI, CT, ultrasound, or other scanning method, wherein the needle  
12 or other handheld device comprises sensing elements for mapping the articular surface).

13 It should be noted that in the digital measuring system and method described  
14 hereinabove (as well as any of the mapping/measuring techniques herein), a second (or  
15 third, etc.) set of data points may be taken, and the subsequent set(s) of data points  
16 compared with the original data points taken, to reduce the margin of error from taking  
17 only a single set of data points. Thus, a software algorithm in a system or method  
18 consistent with the invention may comprise appropriate routines to effect such  
19 comparisons, for error reduction purposes.

20 Those skilled in the art will recognize that the present invention is subject to other  
21 modifications and/or alterations, all of which are deemed within the scope of the present  
22 invention, as defined in the hereinafter appended claims.

23 What is claimed is:
